Flatness Theorem

K is **lattice-free** if $\text{int}(K) \cap \Lambda = \emptyset$

Theorem (Flatness Theorem)

For each dimension d ,

$$W_d := \sup_{K \text{ lattice-free}} \text{width}_\Lambda(K) < \infty.$$

Flatness Theorem

K is **lattice-free** if $\text{int}(K) \cap \Lambda = \emptyset$

Theorem (Flatness Theorem)

For each dimension d ,

$$W_d := \sup_{K \text{ lattice-free}} \text{width}_\Lambda(K) < \infty.$$

Known values: $W_1 = 1$, $W_2 = 1 + 3/\sqrt{2} \simeq 2.1547$ (Hurkens 1990)

Flatness History

- Khinchine 1948: $W_d \leq O(d!)$

Flatness History

- Khinchine 1948: $W_d \leq O(d!)$
- Lenstra 1983: $W_d \in 2^{O(d^2)}$ + poly-time algorithm.

Flatness History

- Khinchine 1948: $W_d \leq O(d!)$
- Lenstra 1983: $W_d \in 2^{O(d^2)}$ + poly-time algorithm.
- Hastad 1986: $W_d \in O(d^{5/2})$.

Flatness History

- Kannan-Lovász 1988: $W_d \in O(d^2)$. NICE PROOF. Def of covering minima.
- Banaszczyk-Litvak-Pajor-Szarek 1999, $W_d \in O(d^{3/2})$.

Flatness History

- Khinchine 1948: $W_d \leq O(d!)$
- Lenstra 1983: $W_d \in 2^{O(d^2)} +$ poly-time algorithm.
- Hastad 1986: $W_d \in O(d^{5/2})$.
- Kannan-Lovász 1988: $W_d \in O(d^2)$. NICE PROOF. Def of covering minima.
- Banaszczyk-Litvak-Pajor-Szarek 1999, $W_d \in O(d^{3/2})$.
Also, $W_d \in O(d \log \min(f_0, f_{d-1}))$ for lattice-free polytopes with at most f_0 vertices and f_{d-1} facets. In particular, $O(d \log d)$ for simplices.

Flatness History

- Khinchine 1948: $W_d \leq O(d!)$
- Lenstra 1983: $W_d \in 2^{O(d^2)} + \text{poly-time algorithm.}$
- Hastad 1986: $W_d \in O(d^{5/2}).$
- Kannan-Lovász 1988: $W_d \in O(d^2).$ NICE PROOF. Def of covering minima.
- Banaszczyk-Litvak-Pajor-Szarek 1999, $W_d \in O(d^{3/2}).$
Also, $W_d \in O(d \log \min(f_0, f_{d-1}))$ for lattice-free polytopes with at most f_0 vertices and f_{d-1} facets. In particular, $O(d \log d)$ for simplices.
- Rudelson 2000 $W_d \in O(d^{4/3} \log^9 d)$

Flatness History

- Khinchine 1948: $W_d \leq O(d!)$
- Lenstra 1983: $W_d \in 2^{O(d^2)} + \text{poly-time algorithm.}$
- Hastad 1986: $W_d \in O(d^{5/2}).$
- Kannan-Lovász 1988: $W_d \in O(d^2).$ NICE PROOF. Def of covering minima.
- Banaszczyk-Litvak-Pajor-Szarek 1999, $W_d \in O(d^{3/2}).$
Also, $W_d \in O(d \log \min(f_0, f_{d-1}))$ for lattice-free polytopes with at most f_0 vertices and f_{d-1} facets. In particular, $O(d \log d)$ for simplices.
- Rudelson 2000 $W_d \in O(d^{4/3} \log^9 d)$

Current “guess”: $W_d \in O(d)$ (perhaps modulo poly-log factors).

Flatness lower bounds

- $W_d \geq d$ is trivial (d -th dilation of unimodular simplex is lattice-free).

Flatness lower bounds

- $W_d \geq d$ is trivial (d -th dilation of unimodular simplex is lattice-free).
- $W_2 = 1 + 2/\sqrt{3} = 2.1547\dots$ (Hurkens 1990).

Flatness lower bounds

- $W_d \geq d$ is trivial (d -th dilation of unimodular simplex is lattice-free).
- $W_2 = 1 + 2/\sqrt{3} = 2.1547\dots$ (Hurkens 1990).
- $W_{d_1+d_2} \geq W_{d_1} + W_{d_2}$, via a [direct sum](#) argument (Codenotti-Santos?).

Flatness lower bounds

- $W_d \geq d$ is trivial (d -th dilation of unimodular simplex is lattice-free).
- $W_2 = 1 + 2/\sqrt{3} = 2.1547\dots$ (Hurkens 1990).
- $W_{d_1+d_2} \geq W_{d_1} + W_{d_2}$, via a [direct sum](#) argument (Codenotti-Santos?).

The last remark has the following consequences:

Corollary

$$\lim_{d \rightarrow \infty} \frac{W_d}{d} = \sup_d \frac{W_d}{d} \geq 1.077\dots$$

Flatness lower bounds

- $W_d \geq d$ is trivial (d -th dilation of unimodular simplex is lattice-free).
- $W_2 = 1 + 2/\sqrt{3} = 2.1547\dots$ (Hurkens 1990).
- $W_{d_1+d_2} \geq W_{d_1} + W_{d_2}$, via a [direct sum](#) argument (Codenotti-Santos?).

The last remark has the following consequences:

Corollary

$$\lim_{d \rightarrow \infty} \frac{W_d}{d} = \sup_d \frac{W_d}{d} \geq 1.077\dots$$

Moreover, the limit is the same if restricted to *lattice polytopes* instead of arbitrary convex bodies.

Width vs. volume, dim 2

Related to the flatness theorem is the fact that lattice-free $(d + 1)$ -bodies of width larger than W_d must have bounded volume.

Width vs. volume, dim 2

Related to the flatness theorem is the fact that lattice-free $(d + 1)$ -bodies of width larger than W_d must have bounded volume.

Theorem (Averkov-Wagner 2012)

Let K be a lattice-free convex 2-body with $w > 1$.

Width vs. volume, dim 2

Related to the flatness theorem is the fact that lattice-free $(d + 1)$ -bodies of width larger than W_d must have bounded volume.

Theorem (Averkov-Wagner 2012)

Let K be a lattice-free convex 2-body with $w > 1$. Then

$$\text{vol}(K) \leq \begin{cases} \frac{w^2}{2(w-1)} & \text{for } w \in (1, 2], \\ \frac{3w^2}{3w+1-\sqrt{1+6w-3w^2}} & \text{for } w \in [2, 1 + \frac{2}{\sqrt{3}}]. \end{cases}$$

The bound is attained iff K is as follows, respectively:

Width vs. volume, dim 3

Theorem (IglesiasValiño-Santos, 2018)

Let K be a lattice-free convex 3-body of lattice width $w > 1 + 2/\sqrt{3} = 2.155$. Then,

$$\text{vol}(K) \leq \begin{cases} \frac{3w^3}{4(w - (1 + 2/\sqrt{3}))}, & \text{if } w \leq \frac{2}{\sqrt{3}}(\sqrt{5} - 1) + 1 = 2.427, \\ \frac{8w^3}{(w-1)^3}, & \text{if } w \geq 2.427. \end{cases}$$

These bound are *not* attained.

Definition

We now concentrate on **lattice polytopes**. $P :=$
convex hull of a finite set of points in Λ .

Definition

We now concentrate on **lattice polytopes**. $P :=$
convex hull of a finite set of points in Λ .

Definition

We now concentrate on **lattice polytopes**. $P :=$
convex hull of a finite set of points in Λ .

Definition

We now concentrate on **lattice polytopes**. $P :=$
convex hull of a finite set of points in Λ .

- P is **hollow** (or lattice-free) if
no lattice points in $\text{int}(P)$

$$2 \neq 3$$

In dimension 3, there are infinitely many (classes of) *empty* simplices.

$$2 \neq 3$$

In dimension 3, there are infinitely many (classes of) *empty* simplices.

$$2 \neq 3$$

In dimension 3, there are infinitely many (classes of) *empty* simplices.

$$2 \neq 3$$

In dimension 3, there are infinitely many (classes of) *empty* simplices.

$$2 \neq 3$$

In dimension 3, there are infinitely many (classes of) *empty* simplices.

$$2 \neq 3$$

In dimension 3, there are infinitely many (classes of) *empty* simplices.

$$2 \neq 3$$

In dimension 3, there are infinitely many (classes of) *empty* simplices.
Yet, they have a nice and relatively simple classification:

$$2 \neq 3$$

In dimension 3, there are infinitely many (classes of) *empty* simplices. Yet, they have a nice and relatively simple classification:

Theorem (White 1964)

*Every empty tetrahedron has **width one**.*

$2 \neq 3$

In dimension 3, there are infinitely many (classes of) *empty* simplices.
Yet, they have a nice and relatively simple classification:

Theorem (White 1964)

Every empty tetrahedron has **width one**.

Hence it is equivalent to $\Delta(p, q) := \text{conv} \{(0, 0, 0), (1, 0, 0), (0, 0, 1), (p, q, 1)\}$,
for some $q \in \mathbb{N}$, $p \in \mathbb{Z}$, $\gcd(p, q) = 1$.

$2 \neq 3$

In dimension 3, there are infinitely many (classes of) *empty* simplices. Yet, they have a nice and relatively simple classification:

Theorem (White 1964)

Every empty tetrahedron has **width one**.

Hence it is equivalent to $\Delta(p, q) := \text{conv} \{(0, 0, 0), (1, 0, 0), (0, 0, 1), (p, q, 1)\}$, for some $q \in \mathbb{N}$, $p \in \mathbb{Z}$, $\gcd(p, q) = 1$.

That is:

There are infinitely many empty tetrahedra, but they form a *two-parameter family* that we can describe completely.

Classification of hollow 3-polytopes

What about *hollow* 3-polytopes?

Theorem

The whole list of hollow 3-polytopes consists of:

- 1) *Those of width one.*
- 2) *Those that project to the dilated unimodular triangle.*

Classification of hollow 3-polytopes

What about *hollow* 3-polytopes?

Theorem

The whole list of hollow 3-polytopes consists of:

- 1 Those of width one.
- 2 Those that project to the dilated unimodular triangle.
- 3 An additional finite list (Treutlein 2008)

Classification of hollow 3-polytopes

What about *hollow* 3-polytopes?

Theorem

The whole list of hollow 3-polytopes consists of:

- 1 Those of width one.
- 2 Those that project to the dilated unimodular triangle.
- 3 An additional finite list (Treutlein 2008) with only twelve maximal elements (Averkov-Krümpelmann-Weltge, 2016): Seven of width two and five of width three.

Classification of hollow 3-polytopes

What about *hollow* 3-polytopes?

Theorem

The whole list of hollow 3-polytopes consists of:

- 1 Those of width one.
- 2 Those that project to the dilated unimodular triangle.
- 3 An additional finite list (Treutlein 2008) with only twelve maximal elements (Averkov-Krümpelmann-Weltge, 2016): Seven of width two and five of width three.

Remark

The three cases (1), (2) and (3) correspond to what is the minimal dimension of a lattice projection of P that is still hollow.

The maximal hollow 3-polytopes (d'après AKW2016)

Hollow projections of hollow polytopes

Finiteness of the number of hollow 3-polytopes that **do not project** to lower dimensions is a general fact:

Theorem (Nill-Ziegler 2011, also Lawrence 1991)

For each d , all except finitely many hollow d -polytopes (in particular, empty d -simplices) project to hollow polytopes of dimension $< d$.

Hollow projections of hollow polytopes

Finiteness of the number of hollow 3-polytopes that **do not project** to lower dimensions is a general fact:

Theorem (Nill-Ziegler 2011, also Lawrence 1991)

For each d , all except finitely many hollow d -polytopes (in particular, empty d -simplices) project to hollow polytopes of dimension $< d$.

... and this result gives a first step towards a classification of empty (or hollow) d -polytopes. To each hollow (or empty) d -polytope P we assign a number $k \leq d$ and a hollow k -polytope Q such that P projects to Q but Q does not project further.

Hollow projections of hollow polytopes

Finiteness of the number of hollow 3-polytopes that **do not project** to lower dimensions is a general fact:

Theorem (Nill-Ziegler 2011, also Lawrence 1991)

For each d , all except finitely many hollow d -polytopes (in particular, empty d -simplices) project to hollow polytopes of dimension $< d$.

... and this result gives a first step towards a classification of empty (or hollow) d -polytopes. To each hollow (or empty) d -polytope P we assign a number $k \leq d$ and a hollow k -polytope Q such that P projects to Q but Q does not project further. The above theorem says that there are finitely many Q 's for each k , hence for each d .

Hollow projections of hollow polytopes

Finiteness of the number of hollow 3-polytopes that **do not project** to lower dimensions is a general fact:

Theorem (Nill-Ziegler 2011, also Lawrence 1991)

For each d , all except finitely many hollow d -polytopes (in particular, empty d -simplices) project to hollow polytopes of dimension $< d$.

... and this result gives a first step towards a classification of empty (or hollow) d -polytopes. The above theorem says that there are finitely many Q 's for each k , hence for each d .

Examples

P projects to a hollow 1-polytope $\Leftrightarrow P$ has width one.

P projects to a hollow 2-polytope $\Leftrightarrow P$ either has width one or projects to the second dilation of a unimodular triangle.

$$3 \neq 4$$

In dimension 4, Haase and Ziegler (2000) experimentally found that:

$3 \neq 4$

In dimension 4, Haase and Ziegler (2000) experimentally found that:

- There are infinitely many empty 4-simplices of width two (e. g., $\text{conv}(e_1, \dots, e_4, v)$, where $v = (2, 2, 3, D - 6)$ and $\text{gcd}(D, 6) = 1$).
- Among the empty 4-simplices of determinant up to 1000 those of width larger than two have determinant ≤ 179 . (There are 178 of width three plus one of width 4 and determinant 101).

$$3 \neq 4$$

In dimension 4, Haase and Ziegler (2000) experimentally found that:

- There are infinitely many empty 4-simplices of width two (e. g., $\text{conv}(e_1, \dots, e_4, v)$, where $v = (2, 2, 3, D - 6)$ and $\text{gcd}(D, 6) = 1$).
- Among the empty 4-simplices of determinant up to 1000 those of width larger than two have determinant ≤ 179 . (There are 178 of width three plus one of width 4 and determinant 101).

Conjecture (H-Z, 2000)

These 179 are the only empty 4-simplices of width > 2 .

$$3 \neq 4$$

In dimension 4, Haase and Ziegler (2000) experimentally found that:

- There are infinitely many empty 4-simplices of width two (e. g., $\text{conv}(e_1, \dots, e_4, v)$, where $v = (2, 2, 3, D - 6)$ and $\text{gcd}(D, 6) = 1$).
- Among the empty 4-simplices of determinant up to 1000 those of width larger than two have determinant ≤ 179 . (There are 178 of width three plus one of width 4 and determinant 101).

Conjecture (H-Z, 2000)

These 179 are the only empty 4-simplices of width > 2 .

On the positive side: Every empty 4-simplex is *cyclic* (Barile et al. 2011).

$3 \neq 4$

In dimension 4, Haase and Ziegler (2000) experimentally found that:

- There are infinitely many empty 4-simplices of width two (e. g., $\text{conv}(e_1, \dots, e_4, v)$, where $v = (2, 2, 3, D - 6)$ and $\text{gcd}(D, 6) = 1$).
- Among the empty 4-simplices of determinant up to 1000 those of width larger than two have determinant ≤ 179 . (There are 178 of width three plus one of width 4 and determinant 101).

Conjecture (H-Z, 2000)

These 179 are the only empty 4-simplices of width > 2 .

On the positive side: Every empty 4-simplex is *cyclic* (Barile et al. 2011). Here, a simplex Δ is called *cyclic* if the quotient group $\Lambda/L(\Delta)$ is cyclic, where $L(\Delta)$ is the lattice spanned by the vertices of Δ .

$3 \neq 4$

In dimension 4, Haase and Ziegler (2000) experimentally found that:

- There are infinitely many empty 4-simplices of width two (e. g., $\text{conv}(e_1, \dots, e_4, v)$, where $v = (2, 2, 3, D - 6)$ and $\text{gcd}(D, 6) = 1$).
- Among the empty 4-simplices of determinant up to 1000 those of width larger than two have determinant ≤ 179 . (There are 178 of width three plus one of width 4 and determinant 101).

Conjecture (H-Z, 2000)

These 179 are the only empty 4-simplices of width > 2 .

On the positive side: Every empty 4-simplex is *cyclic* (Barile et al. 2011). Here, a simplex Δ is called *cyclic* if the quotient group $\Lambda/L(\Delta)$ is cyclic, where $L(\Delta)$ is the lattice spanned by the vertices of Δ .

Observe that $|\mathbb{Z}^d/L(\Delta)|$ equals the *normalized volume* (= the *determinant*) of Δ .

$3 \neq 4$

In dimension 4, Haase and Ziegler (2000) experimentally found that:

- There are infinitely many empty 4-simplices of width two (e. g., $\text{conv}(e_1, \dots, e_4, v)$, where $v = (2, 2, 3, D - 6)$ and $\text{gcd}(D, 6) = 1$).
- Among the empty 4-simplices of determinant up to 1000 those of width larger than two have determinant ≤ 179 . (There are 178 of width three plus one of width 4 and determinant 101).

Conjecture (H-Z, 2000)

These 179 are the only empty 4-simplices of width > 2 .

On the positive side: Every empty 4-simplex is *cyclic* (Barile et al. 2011). Here, a simplex Δ is called *cyclic* if the quotient group $\Lambda/L(\Delta)$ is cyclic, where $L(\Delta)$ is the lattice spanned by the vertices of Δ .

Observe that $|\mathbb{Z}^d/L(\Delta)|$ equals the *normalized volume* (= the *determinant*) of Δ .

$4 \neq 5$: In dimension ≥ 5 there are non-cyclic empty simplices.

The complete classification of empty 4-simplices (Iglesias-S., 2018+)

The complete classification of empty 4-simplices (Iglesias-S., 2018+)

Theorem 1 (volume bound)

All empty 4-simplices that do not project to a hollow 3-polytope have determinant ≤ 7600 .

The complete classification of empty 4-simplices (Iglesias-S., 2018+)

Theorem 1 (volume bound)

All empty 4-simplices that do not project to a hollow 3-polytope have determinant ≤ 7600 .

Theorem 2 (enumeration)

There are 2461 of them. Their determinants range from 24 to 419. There is one of width 4 (determinant=101), 178 of width three (dets. $\in [49, 179]$), and the rest have width two (as predicted by Haase-Ziegler).

The complete classification of empty 4-simplices (Iglesias-S., 2018+)

Theorem 1 (volume bound)

All empty 4-simplices that do not project to a hollow 3-polytope have determinant ≤ 7600 .

Theorem 2 (enumeration)

There are 2461 of them. Their determinants range from 24 to 419. There is one of width 4 (determinant=101), 178 of width three (dets. $\in [49, 179]$), and the rest have width two (as predicted by Haase-Ziegler).

Theorem 3 (infinite families)

All empty 4-simplices that project to hollow 3-polytopes belong to $1 + 3 + 52$ families with 3, 2 and 1 parameters respectively.

The complete classification of empty 4-simplices (Iglesias-S., 2018+)

Theorem 1 (volume bound)

All empty 4-simplices that do not project to a hollow 3-polytope have determinant ≤ 7600 .

Theorem 2 (enumeration)

There are 2461 of them. Their determinants range from 24 to 419. There is one of width 4 (determinant=101), 178 of width three (dets. $\in [49, 179]$), and the rest have width two (as predicted by Haase-Ziegler).

Theorem 3 (infinite families)

All empty 4-simplices that project to hollow 3-polytopes belong to $1 + 3 + 52$ families with 3, 2 and 1 parameters respectively. All of them have width one or two.

Theorem 1

Although we are interested only in *empty* ones, the first theorem holds for all *hollow* simplices:

Theorem 1

All *hollow* 4-simplices that do not project to a hollow 3-polytope have (normalized) volume ≤ 7600 .

Theorem 1

Although we are interested only in *empty* ones, the first theorem holds for all *hollow* simplices:

Theorem 1

All *hollow* 4-simplices that do not project to a hollow 3-polytope have (normalized) volume ≤ 7600 .

We prove this in two parts:

- 1 The case of width at least three.
- 2 The case of width two.

Idea of proof for $\text{width} \geq 3$

Let P be a hollow 4-simplex of width ≥ 3 that *does not project to a hollow 3-polytope*.

Idea of proof for $\text{width} \geq 3$

Let P be a hollow 4-simplex of width ≥ 3 that *does not project to a hollow 3-polytope*.

Consider the lattice projection $\pi : P \rightarrow Q$ along the direction where the *rational diameter* of P is attained.

Q is not hollow, but still has width ≥ 3 .

We call *rational diameter* $\delta(P)$ of P the maximum length (w.r.t. the lattice) of a rational segment contained in P . It equals $\lambda_1^{-1}(P - P)$, where $\lambda_1(C) \equiv$ first successive minimum of C .

Idea of proof for $\text{width} \geq 3$

Let P be a hollow 4-simplex of width ≥ 3 that *does not project to a hollow 3-polytope*.

Consider the lattice projection $\pi : P \rightarrow Q$ along the direction where the *rational diameter* of P is attained.

Q is not hollow, but still has width ≥ 3 .

We call *rational diameter* $\delta(P)$ of P the maximum length (w.r.t. the lattice) of a rational segment contained in P . It equals $\lambda_1^{-1}(P - P)$, where $\lambda_1(C) \equiv$ first successive minimum of C .

Minkowski's first theorem

$$\text{Vol}(P) \leq \frac{\text{Vol}(P - P)}{2^d} \leq d! \delta(P)^d.$$

Idea of proof for width ≥ 3

Let P be a hollow 4-simplex of width ≥ 3 that *does not project to a hollow 3-polytope*.

Consider the lattice projection $\pi : P \rightarrow Q$ along the direction where the *rational diameter* of P is attained.

Q is not hollow, but still has width ≥ 3 .

We call *rational diameter* $\delta(P)$ of P the maximum length (w.r.t. the lattice) of a rational segment contained in P . It equals $\lambda_1^{-1}(P - P)$, where $\lambda_1(C) \equiv$ first successive minimum of C .

Minkowski's first theorem

$$\text{Vol}(P) \leq \frac{\text{Vol}(P-P)}{2^d} \leq d! \delta(P)^d.$$

If P is a simplex this can be improved to

$$\text{Vol}(P) \leq \frac{2^d d!}{\binom{2d}{d}} \delta(P)^d$$

Bounding $\text{Vol}(P)$ from $\text{Vol}(Q)$

Lemma

Let $\pi : P \rightarrow Q$ be an integer projection of a **hollow** d -simplex P onto a **non-hollow** $(d - 1)$ -polytope Q . Let:

- $x \in Q$ be the *Radon point* of the projection.
- δ be the length of $\pi^{-1}(x)$.
- $0 < r < 1$ be the maximum dilation factor such that $Q_r := x + r(Q - x)$ is hollow.

Then:

- 1 $\text{Vol}(P) = \delta \text{Vol}(Q)$.
- 2 $\delta^{-1} \geq 1 - r$.

Bounding $\text{Vol}(P)$ from $\text{Vol}(Q)$

Lemma

Let $\pi : P \rightarrow Q$ be an integer projection of a **hollow** d -simplex P onto a **non-hollow** $(d - 1)$ -polytope Q . Let:

- $x \in Q$ be the *Radon point* of the projection.
- δ be the length of $\pi^{-1}(x)$.
- $0 < r < 1$ be the maximum dilation factor such that $Q_r := x + r(Q - x)$ is hollow.

Then:

- 1 $\text{Vol}(P) = \delta \text{Vol}(Q)$.
- 2 $\delta^{-1} \geq 1 - r$.

- In what follows we project along the direction with $\delta = \text{diameter}(P)$.
- r measures whether Q is “close to hollow” ($r \simeq 1$) or “far from hollow” ($r \simeq 0$)

An upper bound for the volume of empty 4-simplices

Now, suppose that $\pi : P \rightarrow Q$ is the projection along the direction giving the rational diameter of P , so that the δ in the theorem equals the rational diameter of P . We have a dichotomy:

An upper bound for the volume of empty 4-simplices

Now, suppose that $\pi : P \rightarrow Q$ is the projection along the direction giving the rational diameter of P , so that the δ in the theorem equals the rational diameter of P . We have a dichotomy:

- If Q is “far from hollow” then we use Minkowski’s inequality $\text{vol}(P - P) \leq 2^d \delta^d$. Together with $\text{Vol}(P - P) = \binom{2d}{d} \text{Vol}(P)$ (Rogers-Shephard for a simplex):

$$\text{Vol}(P) = \frac{\text{Vol}(P - P)}{\binom{8}{4}} = \frac{24 \text{vol}(P - P)}{\binom{8}{4}} \leq \frac{24 \cdot 16}{\binom{8}{4}} \delta^4 = 5.48 \delta^4.$$

An upper bound for the volume of empty 4-simplices

Now, suppose that $\pi : P \rightarrow Q$ is the projection along the direction giving the rational diameter of P , so that the δ in the theorem equals the rational diameter of P . We have a dichotomy:

- If Q is “far from hollow” then we use Minkowski’s inequality $\text{vol}(P - P) \leq 2^d \delta^d$. Together with $\text{Vol}(P - P) = \binom{2d}{d} \text{Vol}(P)$ (Rogers-Shephard for a simplex):

$$\text{Vol}(P) = \frac{\text{Vol}(P - P)}{\binom{8}{4}} = \frac{24 \text{vol}(P - P)}{\binom{8}{4}} \leq \frac{24 \cdot 16}{\binom{8}{4}} \delta^4 = 5.48 \delta^4.$$

E.g., whenever $r \leq 0.81$ we have $\delta \leq 1/0.19$ and

$$\text{Vol}(P) \leq \frac{5.48}{0.19^4} = 4210.$$

An upper bound for the volume of empty 4-simplices

Now, suppose that $\pi : P \rightarrow Q$ is the projection along the direction giving the rational diameter of P , so that the δ in the theorem equals the rational diameter of P . We have a dichotomy:

- If Q is “close to hollow” then we use the Lemma:

$$\text{Vol}(P) = \delta \text{Vol}(Q) = \frac{\delta}{r^3} \text{Vol}(Q_r), \quad \text{where :}$$

An upper bound for the volume of empty 4-simplices

Now, suppose that $\pi : P \rightarrow Q$ is the projection along the direction giving the rational diameter of P , so that the δ in the theorem equals the rational diameter of P . We have a dichotomy:

- If Q is “close to hollow” then we use the Lemma:

$$\text{Vol}(P) = \delta \text{Vol}(Q) = \frac{\delta}{r^3} \text{Vol}(Q_r), \quad \text{where :}$$

- $\delta \leq 42$ (we skip details).

An upper bound for the volume of empty 4-simplices

Now, suppose that $\pi : P \rightarrow Q$ is the projection along the direction giving the rational diameter of P , so that the δ in the theorem equals the rational diameter of P . We have a dichotomy:

- If Q is “close to hollow” then we use the Lemma:

$$\text{Vol}(P) = \delta \text{Vol}(Q) = \frac{\delta}{r^3} \text{Vol}(Q_r), \quad \text{where :}$$

- $\delta \leq 42$ (we skip details).
- r is bounded away from 0 (by the previous case we can assume $r \geq .81$).

An upper bound for the volume of empty 4-simplices

Now, suppose that $\pi : P \rightarrow Q$ is the projection along the direction giving the rational diameter of P , so that the δ in the theorem equals the rational diameter of P . We have a dichotomy:

- If Q is “close to hollow” then we use the Lemma:

$$\text{Vol}(P) = \delta \text{Vol}(Q) = \frac{\delta}{r^3} \text{Vol}(Q_r), \quad \text{where :}$$

- $\delta \leq 42$ (we skip details).
- r is bounded away from 0 (by the previous case we can assume $r \geq .81$).
- Q_r is a lattice-free 3-polytope of width at least $3r \geq 2.43$, which gives an upper bound for $\text{Vol}(Q_r)$.

An upper bound for the volume of empty 4-simplices

Now, suppose that $\pi : P \rightarrow Q$ is the projection along the direction giving the rational diameter of P , so that the δ in the theorem equals the rational diameter of P . We have a dichotomy:

- If Q is “close to hollow” then we use the Lemma:

$$\text{Vol}(P) = \delta \text{Vol}(Q) = \frac{\delta}{r^3} \text{Vol}(Q_r), \quad \text{where :}$$

- $\delta \leq 42$ (we skip details).
- r is bounded away from 0 (by the previous case we can assume $r \geq .81$).
- Q_r is a lattice-free 3-polytope of width at least $3r \geq 2.43$, which gives an upper bound for $\text{Vol}(Q_r)$.

Putting this together we get “Theorem 2”:

$$\text{Vol}(P) \leq \frac{\delta}{r^3} \text{Vol}(Q_r) \leq \dots \leq 7600$$

A bound on the volume of wide 3-polytopes

Lemma (Iglesias-S. 2017+, inspired in AKW 2016)

Let K be a hollow convex 3-body of width $w > 1 + \frac{2}{\sqrt{3}} = 2.155$. Then,

$$\text{vol}(K) \leq \begin{cases} 8w^3/(w-1)^3, & \text{if } w \geq \frac{2}{\sqrt{3}}(\sqrt{5}-1) + 1 = 2.427, \\ 3w^3/4(w - (1 + 2/\sqrt{3})), & \text{if } w \leq 2.427. \end{cases}$$

Idea of proof for width = 2

Let P be a hollow lattice 4-simplex of width = 2 that *does not project to a hollow 3-polytope*.

Idea of proof for width = 2

Let P be a hollow lattice 4-simplex of width = 2 that *does not project to a hollow 3-polytope*.

W.l.o.g. suppose $P \subset [-1, 1] \times \mathbb{R}^3$, and let $Q = P \cap (\{0\} \times \mathbb{R}^3)$. Then, by Schwarz symmetrization:

$$\text{Vol}(P) \leq 2^4 \text{Vol}(Q).$$

Hence, it suffices to show that $\text{Vol}(Q) \leq 7600/16 = 475$.

Idea of proof for width = 2

Let P be a hollow lattice 4-simplex of width = 2 that *does not project to a hollow 3-polytope*.

W.l.o.g. suppose $P \subset [-1, 1] \times \mathbb{R}^3$, and let $Q = P \cap (\{0\} \times \mathbb{R}^3)$. Then, by Schwarz symmetrization:

$$\text{Vol}(P) \leq 2^4 \text{Vol}(Q).$$

Hence, it suffices to show that $\text{Vol}(Q) \leq 7600/16 = 475$.

Observe Q is half-integer. Two cases:

- ① $\text{width}(Q) \geq 5/2 \Rightarrow$ since Q is hollow,

$$\text{Vol}(Q) = 6 \text{vol } Q \leq 6 \frac{8(5/2)^3}{(3/2)^3} = 222.2$$

Idea of proof for width = 2

Let P be a hollow lattice 4-simplex of width = 2 that *does not project to a hollow 3-polytope*.

W.l.o.g. suppose $P \subset [-1, 1] \times \mathbb{R}^3$, and let $Q = P \cap (\{0\} \times \mathbb{R}^3)$. Then, by Schwarz symmetrization:

$$\text{Vol}(P) \leq 2^4 \text{Vol}(Q).$$

Hence, it suffices to show that $\text{Vol}(Q) \leq 7600/16 = 475$.

Observe Q is half-integer. Two cases:

- ① $\text{width}(Q) \geq 5/2 \Rightarrow$ since Q is hollow,

$$\text{Vol}(Q) = 6 \text{vol } Q \leq 6 \frac{8(5/2)^3}{(3/2)^3} = 222.2$$

- ② $\text{width}(Q) \leq 2 \Rightarrow$ we apply to the middle slice of Q (call it R) the same ideas: R is a lattice-free polygon which does not project to dimension 1 \Rightarrow (we skip details...) $\text{Vol}(Q) \leq 324$

Empty 4-simplices of prime volume

Motivated by their equivalence to *terminal quotient singularities*, Mori, Morrison and Morrison (1989) studied empty 4-simplices of *prime determinant* and found that:

- 1 There are $1+1+29$ infinite families with three, two, and one parameters respectively.
- 2 Up to determinant 419 there are some 4-simplices not in those families, but between 420 and 1600 there are none.

Empty 4-simplices of prime volume

Motivated by their equivalence to *terminal quotient singularities*, Mori, Morrison and Morrison (1989) studied empty 4-simplices of *prime determinant* and found that:

- 1 There are $1+1+29$ infinite families with three, two, and one parameters respectively.
- 2 Up to determinant 419 there are some 4-simplices not in those families, but between 420 and 1600 there are none.

CONJECTURE 1.4 (four-dimensional terminal lemma). *Fix $p \geq 421$. Up to the actions of $(\mathbf{Z}/p\mathbf{Z})^*$ and \mathbf{S}^4 , each isolated four-dimensional terminal $\mathbf{Z}/p\mathbf{Z}$ -quotient singularity of index p is associated with one of the p -terminal quintuples given in Theorem 1.3.*

This conjecture was proved (modulo the “finitely many exceptions”) by Bover (2009) (partially by Sankaran 1990)

Empty 4-simplices of prime volume

Motivated by their equivalence to *terminal quotient singularities*, Mori, Morrison and Morrison (1989) studied empty 4-simplices of *prime determinant* and found that:

- 1 There are $1+1+29$ infinite families with three, two, and one parameters respectively.
- 2 Up to determinant 419 there are some 4-simplices not in those families, but between 420 and 1600 there are none.

CONJECTURE 1.4 (four-dimensional terminal lemma). *Fix $p \geq 421$. Up to the actions of $(\mathbf{Z}/p\mathbf{Z})^*$ and \mathbf{S}^4 , each isolated four-dimensional terminal $\mathbf{Z}/p\mathbf{Z}$ -quotient singularity of index p is associated with one of the p -terminal quintuples given in Theorem 1.3.*

This conjecture was proved (modulo the “finitely many exceptions”) by Bover (2009) (partially by Sankaran 1990) \Rightarrow Complete classification of empty simplices of prime volume.

Empty 4-simplices of prime volume

THEOREM 1.3. *Let Q be a quintuple of integers summing to zero, and let p be a prime number. Suppose that either*

- (a) $Q = (\alpha, -\alpha, \beta, \gamma, -\beta - \gamma)$ with $0 < |\alpha|, |\beta|, |\gamma| < p/2$, and $\beta + \gamma \neq 0$, or
- (b) $Q = (\alpha, -2\alpha, \beta, -2\beta, \alpha + \beta)$ with $0 < |\alpha|, |\beta| < p/2$, and $\alpha + \beta \neq 0$, or
- (c) Q is one of the 29 quintuples listed in Table 1.9 and $p > M_Q$.

Then Q is p -terminal.

TABLE 1.9

Theorem 3

(Almost) Theorem 3 (Barile, Bernardi, Borisov and Kantor, 2011)

All but finitely many empty 4-simplices belong to the $29 + 1 + 1$ families of Mori-Morrison-Morrison (1988), all of which have width one or two.

Theorem 3

(Almost) Theorem 3 (Barile, Bernardi, Borisov and Kantor, 2011)

All but finitely many empty 4-simplices belong to the $29 + 1 + 1$ families of Mori-Morrison-Morrison (1988), all of which have width one or two.

This is only true for 4-simplices of *prime* volume.

Theorem 3

(Almost) Theorem 3 (Barile, Bernardi, Borisov and Kantor, 2011)

All but finitely many empty 4-simplices belong to the $29 + 1 + 1$ families of Mori-Morrison-Morrison (1988), all of which have width one or two.

This is only true for 4-simplices of *prime* volume.

The correct version is:

Theorem 3 (Iglesias, Santos, 2018+)

All empty 4-simplices that project to hollow 3-polytopes belong to:

- 1 The 3-parameter family with quintuple $(a, -a, b, c, -b - c)$.
- 2 One of the two 2-parameter families with quintuples $(a, -2a, b, -2b, a + b)$ and $(a, -2a, b, -2b, a + b)$.
- 3 One of the $29 + 23$ one-parameter families given by the 29 quintuples of Mori, Morrison and Morrison (1988) or the **new 23 non-primitive quintuples**.

Cyclic simplices represented as $(d + 1)$ -tuples

Cyclic simplices represented as $(d + 1)$ -tuples

What are these “quintuples”

For each choice of $D \in \mathbb{N}$, a quintuple $v = (v_0, v_1, v_2, v_3, v_4)$ represents “the” cyclic simplex Δ in which v/D are the barycentric coordinates for a generator of $\mathbb{Z}^4/\Lambda(D)$.

Cyclic simplices represented as $(d + 1)$ -tuples

What are these “quintuples”

For each choice of $D \in \mathbb{N}$, a quintuple $v = (v_0, v_1, v_2, v_3, v_4)$ represents “the” cyclic simplex Δ in which v/D are the barycentric coordinates for a generator of $\mathbb{Z}^4/\Lambda(D)$.

Remarks:

- All empty 4-simplices are cyclic (Barile et al 2011), so they can be represented in this way.

Cyclic simplices represented as $(d + 1)$ -tuples

What are these “quintuples”

For each choice of $D \in \mathbb{N}$, a quintuple $v = (v_0, v_1, v_2, v_3, v_4)$ represents “the” cyclic simplex Δ in which v/D are the barycentric coordinates for a generator of $\mathbb{Z}^4/\Lambda(D)$.

Remarks:

- All empty 4-simplices are cyclic (Barile et al 2011), so they can be represented in this way.
- D equals the determinant of Δ .

Cyclic simplices represented as $(d + 1)$ -tuples

What are these “quintuples”

For each choice of $D \in \mathbb{N}$, a quintuple $v = (v_0, v_1, v_2, v_3, v_4)$ represents “the” cyclic simplex Δ in which v/D are the barycentric coordinates for a generator of $\mathbb{Z}^4/\Lambda(D)$.

Remarks:

- All empty 4-simplices are cyclic (Barile et al 2011), so they can be represented in this way.
- D equals the determinant of Δ .
- the v_i 's are integers, and they are important only modulo D .

Cyclic simplices represented as $(d + 1)$ -tuples

What are these “quintuples”

For each choice of $D \in \mathbb{N}$, a quintuple $v = (v_0, v_1, v_2, v_3, v_4)$ represents “the” cyclic simplex Δ in which v/D are the barycentric coordinates for a generator of $\mathbb{Z}^4/\Lambda(D)$.

Remarks:

- All empty 4-simplices are cyclic (Barile et al 2011), so they can be represented in this way.
- D equals the determinant of Δ .
- the v_i 's are integers, and they are important only modulo D .
- if we choose $\sum v_i = 0$ and do not specify D , then a quintuple $(v_0, v_1, v_2, v_3, v_4)$ represents an infinite family of simplices, one for each D .

Interpretation of the quintuples

Each quintuple is a 1-parameter family of empty 4-simplices that project to a particular hollow 3-polytope.

Interpretation of the quintuples

Each quintuple is a 1-parameter family of empty 4-simplices that project to a particular hollow 3-polytope. We get one simplex of determinant D for each choice of $D \in \mathbb{N}$.

Interpretation of the quintuples

Each quintuple is a 1-parameter family of empty 4-simplices that project to a particular hollow 3-polytope. We get one simplex of determinant D for each choice of $D \in \mathbb{N}$. The entries in a quintuple can be interpreted as:

- Divided by D , they are barycentric coordinates for a generator of the (cyclic) group $\mathbb{Z}^4/L(\Delta)$.

Interpretation of the quintuples

Each quintuple is a 1-parameter family of empty 4-simplices that project to a particular hollow 3-polytope. We get one simplex of determinant D for each choice of $D \in \mathbb{N}$. The entries in a quintuple can be interpreted as:

- Divided by D , they are barycentric coordinates for a generator of the (cyclic) group $\mathbb{Z}^4/L(\Delta)$.
- They are homogeneous coordinates for a line $\ell \in \{x \in \mathbb{R}^5 : \sum x_i = 1\} \cong \mathbb{R}^4$ passing through the origin (assumed to be a vertex of Δ). This line gives the projection direction, and has the property that the projection of Δ is hollow.

Interpretation of the quintuples

Each quintuple is a 1-parameter family of empty 4-simplices that project to a particular hollow 3-polytope. We get one simplex of determinant D for each choice of $D \in \mathbb{N}$. The entries in a quintuple can be interpreted as:

- Divided by D , they are barycentric coordinates for a generator of the (cyclic) group $\mathbb{Z}^4/L(\Delta)$.
- They are homogeneous coordinates for a line $\ell \in \{x \in \mathbb{R}^5 : \sum x_i = 1\} \cong \mathbb{R}^4$ passing through the origin (assumed to be a vertex of Δ). This line gives the projection direction, and has the property that the projection of Δ is hollow.
- It gives the (unique) affine dependence among the projection of the vertices of Δ in the direction of the line ℓ .

Interpretation of the quintuples

More generally: a k -parameter family corresponds to the set of all d -dimensional lifts of a certain configuration of $d + 1$ points in dimension $d - k$. The “ k -parameter $(d + 1)$ -tuple” parametrizes the affine dependences among the $d + 1$ points in \mathbb{R}^k .

In particular, the Nill-Ziegler result (“all except finitely many hollow d -polytopes project to a hollow $< d$ -polytope”) implies:

Interpretation of the quintuples

More generally: a k -parameter family corresponds to the set of all d -dimensional lifts of a certain configuration of $d + 1$ points in dimension $d - k$. The “ k -parameter $(d + 1)$ -tuple” parametrizes the affine dependences among the $d + 1$ points in \mathbb{R}^k .

In particular, the Nill-Ziegler result (“all except finitely many hollow d -polytopes project to a hollow $< d$ -polytope”) implies:

Corollary

In any fixed dimension d , the set of all hollow d -simplices can be stratified “à la Mori et al.” into a finite number of “families”. Each family is represented as a k -dimensional rational linear subspace of \mathbb{R}^{d+1} ($k \in \{0, \dots, d - 1\}$). A k -parameter family corresponds to simplices projecting to a particular configuration A of $d + 1$ points in \mathbb{R}^k such that $\text{conv}(A)$ is hollow but does not project to dimension $< d - k$.

Proof of Theorem 3

The list in the statement corresponds to empty 4-simplices projecting to lower dimensional hollow polytopes:

- Simplices projecting to dim 1 (that is, of width one) can a priori project in two ways: “4 + 1” or “3 + 2”. But the classification of 3-dimensional empty simplices implies that the former is a special case of the latter. Affine dependences in the latter are parametrized by $(a, -a, b, c, -b - c)$ (the 3-parameter family of MMM).

Proof of Theorem 3

The list in the statement corresponds to empty 4-simplices projecting to lower dimensional hollow polytopes:

- Simplices projecting to dim 1 (that is, of width one) can a priori project in two ways: “4 + 1” or “3 + 2”. But the classification of 3-dimensional empty simplices implies that the former is a special case of the latter. Affine dependences in the latter are parametrized by $(a, -a, b, c, -b - c)$ (the 3-parameter family of MMM).
- A lattice 4-simplex Δ projecting to dim 2 must project to the second dilation of a unimodular triangle. For Δ to be empty one needs the vertices to project to one of the following configurations:

projection:

aff. dependence: $(a, -2a, b, -2b, a + b)$ $(a, -2a, b, -2b, a + b)$

Proof of Theorem 3 (cont.)

- Lattice 4-simplices projecting to dim. 3 can be exhaustively described via the (finite) classification of hollow 3-polytopes with at most 5 vertices and not projecting to dim two (Averkov et al. 2016).

Proof of Theorem 3 (cont.)

- Lattice 4-simplices projecting to dim. 3 can be exhaustively described via the (finite) classification of hollow 3-polytopes with at most 5 vertices and not projecting to dim two (Averkov et al. 2016).

To narrow the search we use that, of the three types of 3-polytopes with ≤ 5 vertices (tetrahedron, sq. pyramid, triang. bipyramid) only the latter can possibly produce infinitely many hollow 4-dimensional lifts (Blanco-Haase-Hofmann-S. 2016).

Proof of Theorem 3 (cont.)

- Lattice 4-simplices projecting to dim. 3 can be exhaustively described via the (finite) classification of hollow 3-polytopes with at most 5 vertices and not projecting to dim two (Averkov et al. 2016).

To narrow the search we use that, of the three types of 3-polytopes with ≤ 5 vertices (tetrahedron, sq. pyramid, triang. bipyramid) only the latter can possibly produce infinitely many hollow 4-dimensional lifts (Blanco-Haase-Hofmann-S. 2016).

In this way we recover the 29 quintuples of Mori-Morrison-Morrison 1988, **plus 23 additional “non-primitive quintuples”**.

The 29 quintuples

$$\begin{array}{ll}
 \mathbb{Q}\{(9, 1, -2, -3, -5)\} & \mathbb{Q}\{(7, 5, 3, -1, -14)\} \\
 \mathbb{Q}\{(9, 2, -1, -4, -6)\} & \mathbb{Q}\{(9, 7, 1, -3, -14)\} \\
 \mathbb{Q}\{(12, 3, -4, -5, -6)\} & \mathbb{Q}\{(15, 7, -3, -5, -14)\} \\
 \mathbb{Q}\{(12, 2, -3, -4, -7)\} & \mathbb{Q}\{(8, 5, 3, -1, -15)\} \\
 \mathbb{Q}\{(9, 4, -2, -3, -8)\} & \mathbb{Q}\{(10, 6, 1, -2, -15)\} \\
 \mathbb{Q}\{(12, 1, -2, -3, -8)\} & \mathbb{Q}\{(12, 5, 2, -4, -15)\} \\
 \mathbb{Q}\{(12, 3, -1, -6, -8)\} & \mathbb{Q}\{(9, 6, 4, -1, -18)\} \\
 \mathbb{Q}\{(15, 4, -5, -6, -8)\} & \mathbb{Q}\{(9, 6, 5, -2, -18)\} \\
 \mathbb{Q}\{(12, 2, -1, -4, -9)\} & \mathbb{Q}\{(12, 9, 1, -4, -18)\} \\
 \mathbb{Q}\{(10, 6, -2, -5, -9)\} & \mathbb{Q}\{(10, 7, 4, -1, -20)\} \\
 \mathbb{Q}\{(15, 1, -2, -5, -9)\} & \mathbb{Q}\{(10, 8, 3, -1, -20)\} \\
 \mathbb{Q}\{(12, 5, -3, -4, -10)\} & \mathbb{Q}\{(10, 9, 4, -3, -20)\} \\
 \mathbb{Q}\{(15, 2, -3, -4, -10)\} & \mathbb{Q}\{(12, 10, 1, -3, -20)\} \\
 \mathbb{Q}\{(6, 4, 3, -1, -12)\} & \mathbb{Q}\{(12, 8, 5, -1, -24)\} \\
 & \mathbb{Q}\{(15, 10, 6, -1, -30)\}
 \end{array}$$

The 29 quintuples of Mori-Morrison-Morrison. Each represents (the rational points in) a line through the origin, in the 4-torus $\mathbb{R}^4/L(\Delta)$.

The 23 “non-primitive quintuples”

$$\begin{array}{ll}
 (0, 0, \frac{1}{2}, \frac{1}{2}, 0) + \mathbb{Q}\{(6, -2, -12, 4, 4)\} & (0, 0, \frac{2}{3}, \frac{1}{3}, 0) + \mathbb{Q}\{(-9, 6, 3, 3, -3)\} \\
 (\frac{1}{2}, 0, 0, 0, \frac{1}{2}) + \mathbb{Q}\{(8, -6, 2, -8, 4)\} & (\frac{1}{3}, 0, \frac{2}{3}, 0, 0) + \mathbb{Q}\{(9, -9, 3, -6, 3)\} \\
 (0, 0, \frac{1}{2}, 0, \frac{1}{2}) + \mathbb{Q}\{(8, -4, -12, 6, 2)\} & (0, 0, \frac{1}{3}, \frac{2}{3}, 0) + \mathbb{Q}\{(-9, 3, 6, 6, -6)\} \\
 (\frac{1}{2}, 0, 0, 0, \frac{1}{2}) + \mathbb{Q}\{(4, 6, -2, -16, 8)\} & (0, 0, \frac{1}{3}, \frac{2}{3}, 0) + \mathbb{Q}\{(12, -6, -12, 3, 3)\} \\
 (0, \frac{1}{2}, \frac{1}{2}, 0, 0) + \mathbb{Q}\{(2, -12, 4, 12, -6)\} & (\frac{1}{3}, 0, \frac{2}{3}, 0, 0) + \mathbb{Q}\{(9, -18, 6, 6, -3)\} \\
 (\frac{1}{2}, 0, \frac{1}{2}, 0, 0) + \mathbb{Q}\{(12, -16, 8, -6, 2)\} & (\frac{1}{3}, 0, \frac{2}{3}, 0, 0) + \mathbb{Q}\{(12, -18, 3, 6, -3)\} \\
 (0, \frac{1}{2}, 0, 0, \frac{1}{2}) + \mathbb{Q}\{(2, 12, -8, -12, 6)\} & (\frac{1}{3}, 0, \frac{2}{3}, 0, 0) + \mathbb{Q}\{(12, -9, 3, -12, 6)\} \\
 (\frac{1}{2}, 0, 0, 0, \frac{1}{2}) + \mathbb{Q}\{(8, 6, -2, -24, 12)\} & (\frac{1}{3}, 0, \frac{2}{3}, 0, 0) + \mathbb{Q}\{(6, -3, 6, -18, 9)\} \\
 (0, \frac{1}{2}, 0, 0, \frac{1}{2}) + \mathbb{Q}\{(6, -2, 8, -24, 12)\} & (0, 0, \frac{1}{3}, \frac{1}{3}, \frac{1}{3}) + \mathbb{Q}\{(3, -18, 6, 18, -9)\} \\
 \\ \\
 (\frac{1}{2}, \frac{1}{4}, \frac{1}{4}, 0, 0) + \mathbb{Q}\{(12, -12, 4, -8, 4)\} & (\frac{1}{6}, 0, 0, \frac{2}{3}, \frac{1}{6}) + \mathbb{Q}\{(6, -18, 6, 12, -6)\} \\
 (0, \frac{1}{4}, \frac{1}{4}, 0, \frac{1}{2}) + \mathbb{Q}\{(4, 8, -4, -16, 8)\} & \\
 (0, 0, \frac{1}{4}, \frac{1}{2}, \frac{1}{4}) + \mathbb{Q}\{(4, -16, 4, 16, -8)\} & \\
 (0, \frac{1}{4}, \frac{1}{4}, 0, \frac{1}{2}) + \mathbb{Q}\{(4, 12, -4, -24, 12)\} &
 \end{array}$$

The 23 non-primitive quintuples. Each represents (the rational points in) a line in $\mathbb{R}^4/\Lambda(\Delta)$ not passing through the origin.

Theorem 2 (enumeration)

Theorem 2 (Iglesias-S., 2017+)

With determinant ≤ 7600 there are 2461 empty 4-simplices that do not project to hollow 3-polytopes. Their determinants range from 24 to 419.

Theorem 2 (enumeration)

Theorem 2 (Iglesias-S., 2017+)

With determinant ≤ 7600 there are 2461 empty 4-simplices that do not project to hollow 3-polytopes. Their determinants range from 24 to 419.

The proof is via an exhaustive computer enumeration.

Theorem 2 (enumeration)

Theorem 2 (Iglesias-S., 2017+)

With determinant ≤ 7600 there are 2461 empty 4-simplices that do not project to hollow 3-polytopes. Their determinants range from 24 to 419.

The proof is via an exhaustive computer enumeration.

Note: It is easy to prove (by induction on the dimension) that there are finitely many lattice polytopes of a given dimension d and with normalized volume bounded by D , for every $d, D \in \mathbb{N}$ (e.g., Lagarias-Ziegler, 1991).

The algorithm implicit in the general proof is impracticable, but for the case of simplices another methods can be used.

Enumeration algorithms

To enumerate all empty 4-simplices of a given volume D we use one of two algorithms:

Enumeration algorithms

To enumerate all empty 4-simplices of a given volume D we use one of two algorithms:

- Algorithm 1: **If D has less than 5 prime factors**, then every empty 4-simplex Δ of volume D has a unimodular facet (because Δ is cyclic, by Barile et al. 2011, which implies the volumes of facets are relatively prime). Thus, Δ is equivalent to

$$\text{conv}\{e_1, e_2, e_3, e_4, v\},$$

for some $v = (v_1, v_2, v_3, v_4) \in \mathbb{Z}^4$ with $\sum v_i = D + 1$. Moreover, v needs only to be considered modulo D , which gives a priori D^3 possibilities.

Enumeration algorithms

To enumerate all empty 4-simplices of a given volume D we use one of two algorithms:

- Algorithm 1: **If D has less than 5 prime factors**, then every empty 4-simplex Δ of volume D has a unimodular facet (because Δ is cyclic, by Barile et al. 2011, which implies the volumes of facets are relatively prime). Thus, Δ is equivalent to

$$\text{conv}\{e_1, e_2, e_3, e_4, v\},$$

for some $v = (v_1, v_2, v_3, v_4) \in \mathbb{Z}^4$ with $\sum v_i = D + 1$. Moreover, v needs only to be considered modulo D , which gives a priori D^3 possibilities.

- Algorithm 2: **If D has at least 2 prime factors**, then we can decompose $D = pq$ with p and q relatively prime. Every 4-simplex Δ_D of volume D can be obtained by “merging” simplices Δ_p and Δ_q of volumes p and q .

Computational performance data

More than 10000 hours of computation have been used.

Computational performance data

More than 10000 hours of computation have been used.
Algorithm 2 is much slower than Algorithm 1 if $p \ll q$, and slightly faster than Algorithm 1 if $p \simeq q$.

Computation time (seconds) for the list of all empty lattice 4-simplices of a given volume

The “finitely many exceptions”

The enumeration gives us the 2461 empty 4-simplices that do not belong to the infinite families of Theorem 3. Their determinants range from 24 to 419.

Those of width ≥ 3 coincide with the list computed by Haase and Ziegler (2000): there are 178 of width three (with determinants in $[49, 179]$ and exactly one of width 4 (with determinant 101 and quintuple $(-1, 6, 14, 17, 65)$).
